Abstract

Cuneiform character recognition represents a complex problem in pattern recognition as result of problems that related to style of this type of writing and the diversity of its features according to distortion and shadows problems. This research proves that polygon approximation method is an optimal feature extra action method , which has been adopted for recognition task compeer with elliptic Fourier descriptor, according to the achieved high accuracy recognition results after applying multiple classes of support vector machine classifier along with depending on its discriminate functions .This work is applied by using two Data set , the first one contains 320 images of cuneiform symbols patterns for evaluate the optimal feature extraction method. The second contains 240 images of cuneiform characters to evaluate the recognition system, agents training dataset consists of 2D four triangular patterns.

1. Introduction

Cuneiform writing is one of the oldest language systems which emerged in the third millennium BC, where the first character of writing was invented in Urk city in south of Iraq. Writing system is subjected to many stages of development to facilitate its characteristics about the shape of symbols and numbers that represent a development state of old Sumerian scrip language to Babylonian and Assyrian cuneiform language. At the beginning of the 19th century thousands of cuneiform tablets were discovered In Iraq and Iran, Which represent various Assyrian Babylonian and Persian civilizations. Today these tablets reside in many museums and the process of interpretation requires experience and time .However, the need for information technology was required to solve this problem about recognition task, therefore this research² presents a recognizing way for the cuneiform symbols by applying OCR principle, through applying its chine sequential principals steps (preprocessing , segmentation , feature extraction and classification). The aim of research is to review a comparison state on features extraction methods, particularly between elliptic Fourier descriptor and polygon approximation methods to evaluate which one of them is adopted to design a recognition system. Where the adopted classifier is a support vector machine (SVM) according its discriminant functions. Finally, it must be noted in this research that the cuneiform character will be treated via collecting of cuneiform symbols, each of them will be classified according to two factors: the first one is to determine the cuneiform patterns and the second is related to its direction.

2-Literature Review

In 2017 Rahma.A. proposed a new method for recognized cuneiform symbols by adopting a polygon approximation as features extraction method. Where K-nearest neighbor classifier is adopted and the recognition raita that was achieved is 91% [1] .In 2014 Mostofi f. proposed intelligent recognition system for Ancient Persian Cuneiform Characters that is based on supervised back propagation neural network model, (classification model). The training data set is created by subjecting the original training set to Gaussian Filter with different values of stander devotion. The otsu's binirized model was adopted for computing global threshold value. The recognition achieved rate was 89-100 %,[2].In 2013 Naktal M. proposed a method for recognizing the cuneiform symbols depending on statistical and structure features derived by projection histogram, center of gravity

Ali .A/ Abdul Monem .S/ Abdul Mohssen .j

and connected component features. However to separate each distinguish feature according to each class of symbols, the k-mean clustering was used. Multilayer Neural Network (MLP) was applied for classifying a task where the recognition rate of accuracy level was different according to each class from 83.3% to 95.1%[3].In 2001 Al-Aany proposed recognition approach for cuneiform symbols depending on extract recognition features that generated from binary cuneiform image symbol by depending on suggested seven transform forms applied on each pixel's with their neighbors. However, each cuneiform symbol will have distinguish features related to directions used for recognition task .The classification process is by indexing process that was implemented distributed on tree structure [4].

3-Cuneiform writing

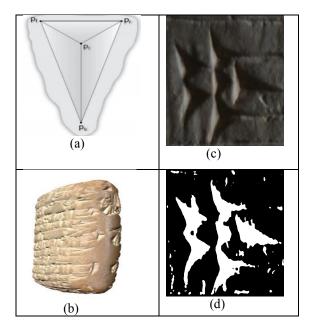

The Assyrian cuneiform language represents one of the stages of the development of cuneiform writing in Mesopotamia, which continued from the beginning of the first millennium to 600 BC. It relies on drilling cuneiform symbols on clay tablets or tablets of stone from left to right to form cuneiform groups which reflect the basic language meanings. This language consists of a set of letters. Each one consists of one or set of cuneiform symbols, these symbols or wedges are organized in different directions either horizontal, vertical, Oblique or diagonal, therefore, these letters with their symbols vary from one character to another according to the (number of symbols, their direction and their location)[5] figure (1)

Figure (1) cuneiforms character images from Iraqi museum

The problems related with recognition tasks have more than one face. The First problem relates to the nature of the writing medium, whether it is stone or clay(2.c), with a three-dimensional writing form. The second relates to the nature of geometry of the cuneiform symbol, which takes the three-dimensional form (three surfaces) figure(2.a),The third problem is the cuneiform writing style, it does not depend on writing on one face but may take writing on all the surfaces of the tablet [5], figure(2.b).

The last problem that interfaces the cuneiform recognition relates with undesirable results like spots after being subjected to segmentation process, figure (2.d), where their features differ from one image to another which affect negatively on the recognition task [1].

Figure(2) cuneiform writing style . a) the 3-D geometry shape of cuneiform symbol , b) the style of cuneiform writing take more than one surface. ,c) cuneiform image character ,d) spots problem

4. Image enhancement:

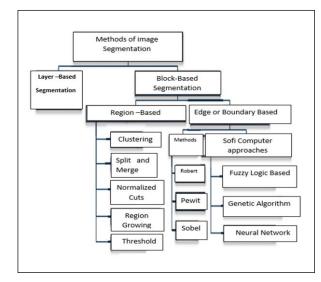

Image enhancement is one of the most important image processing techniques, which leads to reconstruct the image's features to suit the nature of application's requirements . The primary objective is to treat all the associated problems related with blurring ,contrast and noise. The process of enhancement task takes two directions: the first one submits to human vision as criterion for the evaluation, and the second is moving towards supporting and improving image qualities used to support the identity process by machine vision. Enhancement techniques can be classified into two categories[6]:

- 1- Frequency Domain.
- 2- Spatial Domain.

In this research the frequency domain is adopted for applying the enhancement process as the ideal low pass filter.

5.Image segmentation.

It is an image processing technique that leads to segment the image's pixel to segments of regions where each of them has distinguished labels. This simplification process is used to simplify images features to easier or meaningful feature form to be used to support the advanced analysis's or recognition stages. Image segmentation techniques are categorized into two branches: its block and layer based segmentation as seen in following figure (3) [7].

Figure(3):image segmentation techniques

Thresholding is a popular image segmentation technique that is adopted by large number of binriztion methods. It leads to separate the image into two sets group of regions based on selected threshold value (T). If pixel intensity color value is larger than the threshold, it will represent foreground region in the opposite case. It is considered as background, as mathematical formula below.

$$G(x,y) = \begin{cases} 1, if f(x,y) > T \\ 0, if f(x,y) < T & \dots(1) \end{cases}$$

Therefore,to apply image segmentation by thresholding, two formals are adopted to apply this task, these are Niblack and Sauvola's method and choosing one of them depends on statistical Skewness metric [1].

6-Image labeling by Extraction of Connected Components

To reach to labeled image, (Multi-scan strategy) will be applied (which is represented by **Extraction of Connected Components**) on binary image, A as it contains foreground pixels with labeled value equals (1) and background, their pixel labeled value is (0). This process is implemented iteratively with restricted condition depending on dilation concepts.

Initial step starts by locating the first foreground pixel (p) which it represents seed point for reconstructed matrix X_K with the structure element *B*, scan the image *A* for computing the following form[8],[9].

$$X_k = (X_{k-1} \oplus B) \cap A, \quad k = 1, 2, 3, \dots$$
 ...(2)

let $X_0=p$ where K=0,1,2...n

This iterative process would be terminated after the terminated condition was satisfied as $X_{K}=X_{K-1}$. For applying image labeling concept, each regenerated connected component will be assigned by **distinguished label** for each connected component element

7. Elliptical Fourier Descriptor:

Elliptical Fourier Descriptor (EFD) represents boundary shape descriptor where the classification feature is generated from Fourier coefficients [ai,bi,ci,di] about each N harmonic to recognize closed contour of k elements , Where harmonic coefficients are defined as follows[10]:

The closed coordinate points on N harmonic can be calculated as follows :

$$a_{n} = \frac{T}{2n^{2}\pi^{2}} \sum_{i=1}^{k} \frac{dx_{i}}{dt_{i}} \left[\cos \frac{2n\pi t_{i}}{T} - \cos \frac{2n\pi t_{i-1}}{T} \right] ...(3)$$

$$b_{n} = \frac{T}{2n^{2}\pi^{2}} \sum_{i=1}^{k} \frac{dx_{i}}{dt_{i}} \left[\sin \frac{2n\pi t_{i}}{T} - \sin \frac{2n\pi t_{i-1}}{T} \right] ...(4)$$

$$c_{n} = \frac{T}{2n^{2}\pi^{2}} \sum_{i=1}^{k} \frac{dy_{i}}{dt_{i}} \left[\cos \frac{2n\pi t_{i}}{T} - \cos \frac{2n\pi t_{i-1}}{T} \right] ...(5)$$

$$d_{n} = \frac{T}{2n^{2}\pi^{2}} \sum_{i=1}^{k} \frac{dy_{i}}{dt_{i}} \left[\sin \frac{2n\pi t_{i}}{T} - \sin \frac{2n\pi t_{i-1}}{T} \right] ...(6)$$

$$Xi=X_{c+}\sum_{n=1}^{N}a_n\cos\frac{2n\pi t_i}{T}+b_n\sin\frac{2n\pi t_i}{T}\quad \dots (7)$$

Yi=Y_{c+} $\sum_{n=1}^{N} a_n \cos \frac{2n\pi t_i}{r} + b_n \sin \frac{2n\pi t_i}{r}$...(8) Xc and Yc is centroid's coordinate. Defined by below equations.

$$X_{c=\frac{1}{T}}\sum_{I=1}^{K}\frac{dx_{i}}{2d_{i}}(t_{i}^{2}-t_{i-1}^{2})+\beta_{i}(t_{i}^{2}-t_{i-1}^{2}) \quad \dots (9)$$

$$y_{c=\frac{1}{T}} \sum_{l=1}^{K} \frac{dy_{i}}{2d_{i}} (t_{i}^{2} - t_{i-1}^{2}) + \alpha_{i} (t_{i}^{2} - t_{i-1}^{2}) \dots (10)$$

T= The length of chain code.

$$\begin{aligned} & \text{t}_{i} = 1 + (\frac{\sqrt{2} - 1}{2}) (1 - (-1)^{u_{i}}) & \dots (11) \\ & \text{t}_{n} = \sum_{i=1}^{n} dt_{i} & \dots (12) \end{aligned}$$

8. Polygon approximation with Dominant point approaches

In 2007 Asif Masood [11] proposed a new approach for polygon approximation, it is defined as **revers polygonization** principles which provide a good representation about boundary of 2D shapes with high accuracy for data reduction , shape matching and pattern recognition [11]. Basically, this method implementation depends on dominant points (DP) concept , assigned for endpoints of approximated line segments ,where the initial set of (DP) starting with detected break points(BP) is extracted from shape boundary. However, (BP) is derived after applying **freeman's chain code** on shape boundary points. Therefore, any boundary point is defined as break point (BP) that its chain code (Ci) value is not equal the chain code of prior point [12][11], However to apply polygon approximation technique, there are two optimization approaches being used to solve this approximation problem[14][13].

1-Min-\epsilon problems: let polygon **P** vertices to be approximated by another polygon **Q** with predefined number of segments **M** along with minimizing approximation error.

2-Min-# problems: let polygon **P** vertices to be approximated by another polygon **Q** with minimum numbers of segments M, where the error dose not skip the predefined tolerance value

9.Support Vector Machine (SVM)

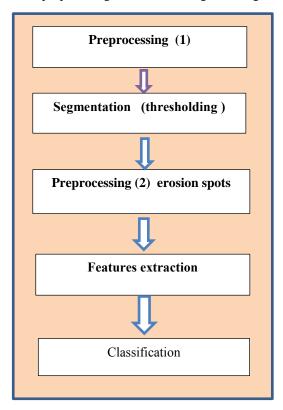

In 1995, Vapnik proposed a binary classification model for the supervised learning, it is a linear classifier in a feature space. Generally, it is a classification task with two classes once the training parameter is determined, however this model is based on custom functions for classification .It is defined as kernel functions. Therefore the SVM algorithm with initial form is like a decision boundary that separates between two classes, but this model can be improved to increase the separation process in new space ,Which results in creating non liner decision boundary (Kernel function). The Kernel functions(K) in table(1) was used by SVM to map input data feature space to high feature space when the training data are not linearly separable[15],[16].

table 1: kernel functions models

Core	Formula
Linear	$\mathbf{K}(\mathbf{x},\mathbf{y}) = \mathbf{x}.\mathbf{y}$
Sigmoid	K(x,y) = tanh(ax.y + b)
Radial Basis	$K(x,y) = \exp(- x-y ^2/\sigma^2)$
Function (RBF)	
Polynomial	$\mathbf{K}(\mathbf{x},\mathbf{y}) = (\mathbf{a}\mathbf{x}.\mathbf{y} + \mathbf{b})^{\mathrm{d}}$

10.Proposed recognition system

This section presents the main diagram figure(4) for cuneiform recognition system starting with preprocessing stage (1)to image segmentation, preprocessing stage (2),features extra action and classification, in addition to review the proposed algorithms according each stage.

Figure(4):proposed recognition system

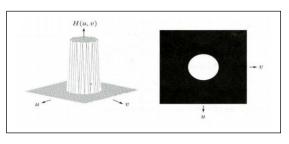

10.1Preprocessing stage (1)

Image enhancement.In this research the frequency domain is adopted for applying the enhancement process. The ideal low pass filter is dependent ,where as ideal low pass filters can be defined as follows:-

:-

$$H(u,v) = \begin{cases} 1 & if \ D(u,v) \le D0 \\ 0 & if \ D(u,v) > D0 \end{cases} \dots (13)$$

Where D0 is non negative value which represents the radios of cutoff frequency and D(u, v) is distance value starting from point to center of frequency figure (5).

Figure(5): ideal low pass filter.

10.2. Image segmentation (Thresholding)

Therefore for applying image segmentation by thresholding, two formals that are adopted to apply this task are Niblack and Sauvola methods, these are defined respectively in following forms, choosing one of them depends on statistical Skewness metric [1].

 $T=M+k\sigma...(14)$

 $T=m(1-k(1-\frac{\sigma}{r}))...(15)$

Where k is constant, (m, σ) represents the mean and standard deviation respectively.

10.3 Preprocessing stage (2)Spot removing

For eliminate the unwanted elements segments like (spots) ,figure(6.b) that resulted from subjecting the gray cuneiform image ,figure (6.a) to thrsholding process. However the target of this process is to create uniform features about cuneiform image symbols to be clear from their elements figure (6.c). Therefore to satisfy this principle, this research adopts the Image connected-component labeling (CCL) concepts to erase the spots according to bellow algorithm .This process get satisfied after applying bellow Algorithm several times to extra each connected elements and assign distinguish label for each one and apply the erosion process for each segments which has small ratio to all image's pixels.

Algorithm (1) : Connected Components Extraction. Input :Binary image. Output : Connected Components image

Step1: read input binary image IB Step2: locate the first foreground pixel p and it's location p(x,y). Step3:initlize the stricture element B. Where $B = \{1 \dots 9\} = 1$; Step4:k=0; Step4:intilize the connection component matrix $X_{\kappa}(0,0).$ Step5 :set $X_K(x,y) = p(x,y)$. Step6: repeat Y=Xk Applied the dilation process on X_k and interest the result with original Image *IB* as following formula. $X_{k+1} = dilation(B, X_K) \cap IB$. K=K+1. Untiled ($Y == X_{K+1}$) Step7: set CC MATRIX=Y. Step8:return (CC MATRIX).

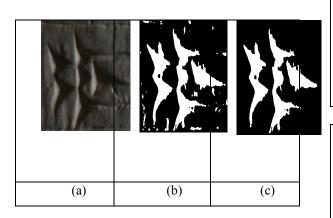

Figure (6) spots erosion a) cuneiform image ,b) binary image with spots ,c) spots off image

10.3.Feature extraction

This section presents two features extraction methods depending on boundary pixels to apply the comparison state between them

10.3.1Feature extraction by Elliptical Fourier Descriptor (EFD).

The features vector generated by EFD is based on quadruple Fourier coefficient (ai, bi.ci, di) values that are defined by equations (3-6) ,where the predefined number of harmonic N, determines the size of features vector. That means that each one of these four parts corresponds to the quadruple coefficient sequentially and its length agrees with degree of harmonic. However, for extracting the boundary coefficient to generate quadruple Fourier coefficient, each cuneiform image's symbol is subjected to extract its boundary by (canny operators) as closed contour to generate freeman chain code that leads to determine the length of chain (T) as seen in figure (7). The Elliptical Fourier algorithm works follows:

6				
Algorithm 2: quadruple Fourier oefficient Input: cuneiform binary image symbol Output:. Fourier coefficient (<i>ai,bi.ci,di</i>)				
Step1: read binary image symbol $I_{s.}$ step2: extract boundary pixels of cuneiform symbol by edge detection method and save the results which represent a boundary image $I_{B.}$ Strp3: apply the thinning operation on boundary pixel. Step4: compute edge encoding process to generate freeman direction code U_i . where $U_{i=\{0,1,2,3,4,5,6,7\}}$. Step5: compute the length of previous direction code d_i				
Where $dt_i = 1 + \left(\frac{\sqrt{2}-1}{2}\right) * (1-(-1)^{ui})).$ Step6: compute the harmonic coefficient (<i>ai,bi.ci,di</i> .)

Figure (7) Elliptical Fourier Descriptors ,a) binary cuneiform symbols, b) boundary image . c)approximated boundary figure ,d) matching class .

10.3.2 Feature extraction by polygon approximation with dominate point

The proposed algorithm to generate features vectors about each cuneiform symbols depends on combining the approximation principals (Min- ϵ problems, Min-# problems) in approximation approaches as illustrated in (7). That means briefly with first approximation principles (Min- ϵ) the number of segments determined previously is compatible with same number of cuneiform classis segments as seen in figure(11) and the tolerance value will be pre-defined where it decreases gradually in each iteration until the termination condition gets satisfied,[1]. The termination condition is satisfied if the number of segments equals the number of one the cuneiform patterns segments (3,5,7,9). the proposed algorithm is as follows:-

Algorithm 3:Polygon approximation				
Input: binary cuneiform image.				
Output: approximated points				
Stor 1. and his and in a second of T				
Step1 : read binary image symbol I_s				
Step2 : apply edge detection method with suitable				
filter,				
Step3 : apply thinning technique ;				
Step4 : compute Freeman's chain code for				
boundary.				
Step5 : find break points DP_b .				
Repeat				
Step6 : compute AVE for all DP				
Step7: repeat				
Step8 : determine DP that minimum value DP _{min}				
-				
Step9 : remove DP _{min} from dominat table				
Step10 : recalculate AVE for DP _{min} 's adjacent				
neighbor.				
Step11: compute max error				
step12: until (max error <th)< td=""></th)<>				
step13 : $z_{=}$ Remaining points about DP's is				
approximate polygon points				
step14: deleted all DP'S which construct with its				
neighbors a straight angle				
step15 : th=th-eps; < eps epsilon value ex=0.009 >				
step16 : until (($z=3$)or($z=5$)or($z=7$)or($z=9$))				
step 17: end <where head="" of="" z="number"></where>				
sup 17. Chu \where Z = humber of field >				

step 18: return approximate points vector .

the recognition process depends on generating a **features vector** for the training set and testing symbol, as illustrated in figure (8), where each feature vector consists of Cartesian coordinate (approximate points) for each class.

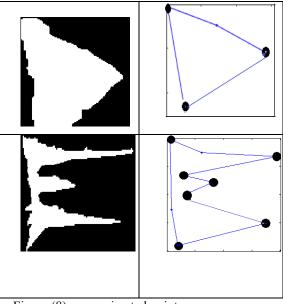

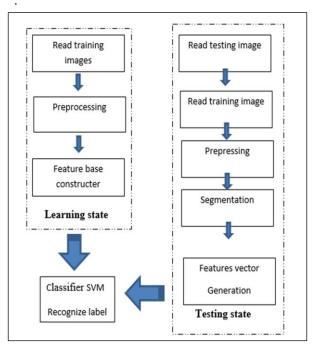

Figure (8): approximated points.

10.4 Classification

The classification task is applied with each cuneiform symbols by SVM classifier as a generated feature vector is adopted **for each features extraction method**, to apply the comparison state. However, the classification stage concerns with two steps. The First one is a training state to generate features base with assigning a distinguished labile for each class (triangle class) .The other step applies the classification task with test feature vector. Below is the classification diagram figure (9).

Figure(9): classification diagram steps.

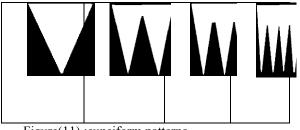

However, after applying the multiple classification task for each symbol the constructed recognition code consists of three parts , which represent number of cuneiform symbol distributed to numbers of vertical, horizontal and diagonal. For example as seen in figure (10) below the cuneiform character, the recognition code (6#2#1#3) which means the total cuneiform symbols equals 6 , which are distributed to 2 vertical ,1 horizontal and 3 diagonal.

Figure(10):cuneiform character.

11.Proposed training dataset

The design of the dataset is one of the most important aspects that play an important role in the classification process. Therefore this proposed training dataset is a virtual dataset consists of 2D four triangular patterns with forms compatible with three-dimensional geometric shape form of the cuneiform symbols, figure (11) . Covering all the possibilities and situations is taken by the cuneiform character's symbols with different directions (horizontal, vertical or diagonal), and compatible with patterns of cuneiform symbols to solve the problem of shadows. These patterns are distributed in 16 classes compatible with cuneiform directions.

Figure(11) :cuneiform patterns

11.Results and discussion:

This section presents the evaluation state according to features extraction metrics (EFD and polygon approximation) **.The first testing state** consists of 320 symbols related to probabilities of conform symbols to determine the recognition accuracy. Therefore, each binary cuneiform symbol is subjected to extra boundary pixels and thinning process to generate features vectors according to each method of comparison state. Therefore, **the second experiment state** which deals with cuneiform character dataset consists of 240 of cuneiform image characters, after evaluating the comparison state. However after applying the first testing process the recognition accuracy with average **processing time** is illustrated in the following tables (table 2) according to each feature extraction method.

Table 2: Comparison of recognition results about each features extraction method with processing time.

Experiment/n	Classification approaches	Accuracy results with (EFD)	Processing time	Accuracy results with (Polygon approximation)	Processing time
1	SVM with	0.6093	0.332	0.940	0.452
	RBF kernel				
2	SVM	0.6845	0.322	0.925	0.421
	with				
	polyn-				
	omial				
	kernel				
3	SVM	0.6594	0.320	0.613	0.441
	with				
	linear				
	kernel				

As seen in previous table, the higher recognition result is achieved when polygon approximation method is adopted to construct features vector especially with RBF discriminate function (Experiment 1). Therefore, to evaluate the reliability about the proposed features extraction method the previous testing set is subjected to resizing process according to the different sizes. Bellow the accuracy results about each size is illustrated in table (3)

Table 3: Comparison of recognition results according to different image sizes, where the SVM classifier is adopted with RBF function.

Image size	Accuracy
256x256	0.940
128x128	0.865
64x64	0.853

Along with applying Gaussian filter on testing set many times according each standard deviation values δ as seen in figure (12) to evaluate the recognition reliability.

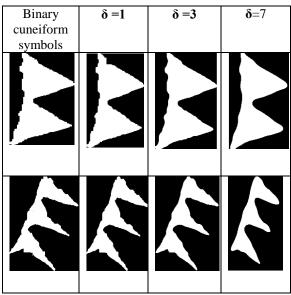

Figure (12): sample of conform symbol deformation. applied Gaussian filter on each cuneiform symbols (in first dataset) with different values of each standard deviation.

Therefore, the first dataset is subjected to deformation process by Gaussian filter several times according to each experiment depending on different standard deviation value, the accuracy results are illustrated in table (4).

standard	Accuracy
deviation value	
1	0.860
3	0.867
4	0.870
7	0.860

However, now after adopting the polygon approximation with SVM classifier, according to its discriminant function (RBF) the recognition result about the **second dataset** is satisfied against each cuneiform character image which can be seen in the following figure(13), where the recognition state for each character results from a cumulative

Cuneiform character image	Recognition text image
X	ŦŦ
	*#
ETT	≻₩
Aligh	王臣
ET W	ΈΨΨ

recognition process.

Figure(13): cuneiform character image sample recognized by proposed system.

When adopting spatial low pass filter domain for enhancement process (according to the second dataset) the output of accuracy character recognition results are illustrated in following table (Table 4):-

Table 4:Comparison of results of recognitionaccuracy ratio after applying different LPF withdifferent sizes

Medina 0.496 0.512 0.496 Gaussian 0.536 0.440 0.512 Average 0.472 0.544 0.504	Filter size	3X3	5X5	7X7
	Medina	0.496	0.512	0.496
Average 0.472 0.544 0.504	Gaussian	0.536	0.440	0.512
	Average	0.472	0.544	0.504

Table 5: Comparison of recognition accuracy results

Experi ment/no	Cutoff frequenc y values	accuracy
1	0.2	0.51
2	0.4	0.61
3	0.6	0.94
4	0.8	0.62
5	0.9	0.67

As seen in the previous table (5), the higher accuracy character recognition is archived in experiment (3), where the value of cut off frequency equals (0.4).

Now the evaluated recognition state is applied among the discriminant functions about SVM with (second dataset), where the value of cutoff frequency equals (0.4) .bellow are accuracy character recognition values and processing time in table (6).

Exp erim ent/n o	Discriminant function	Accu racy	Average Processi ng Time(s)
1	RBF	0.92	4.028
2	liner	0.77	4.136
3	polyn omial	0.75	4.418

As it can be seen in the previous table, the highest accuracy character recognition with low processing time when adopting the RBF is compared with other discriminant functions LPF..

Conclusion

This research presents a comparison state between two feature extracting methods ,the elliptic Fourier descriptor (EFD) and polygon approximation methods, where the support vector machine is adopted as a classifier model with its discriminant kernel functions .Consequently, the evaluated recognition results indicate that the polygon approximation by dominate points is more accurate to be adopted in classification model as the achieved accuracy result is 94% with RBF kernel function compared with (EFD) method. To achieve more reliable decision about the polygon approximation method, the testing set is subjected to deformation state by Gaussian filter with different values of stander divisions, accordingly, the accuracy result is maintained to high quality .The testing state is applied by two testing data set. The frequency domain with low pass enhancement filter is more accurate than the spatial domain according to the accuracy of the achieved results that were compared between them..

المستخلص:

يهدف هذا البحث الى اجراء مقارنه بين طريقتي بناء متجه الصفات بين طريقة تقارب المنحنى وطريقة الواصف الأهليجي الدوري مع بيان اي الطريقتين يمكن اعتمادها في انشاء متجه الصفات ،وذلك اعنمادا على النتائج المتحققه المتمثله بعاملي الوقت والدقة. اظهرت النتائج المتحققه الى تغوق الطريقىه الأولى في بناء متجه الصفات على الطريق الثانية . تم ومن خلال البحث اجراء الأختبارات المطلوبه على مجموعتي اختبار ،الأولى مكونه من ٣٢٠ ثنائية اللون لأختبار اي الطريقتين افضل في بناء متجه الصفات . اما مجموعة اليانات الأختبارية الثانيه فهي مكونه من ٢٤٠ ثنائية اللون الحروف المسماريه الأشوريه يتم اختبارها بعد استكمال المرحله الأولى .تم اعتماد المصنف الدعم بواله المميزه الخطيه ،متعدده الحدود وداله توزيع كاوس. حيث اثبتت النتائج الأختباره على افضليه الاتجاهي بدواله المميزه المعمارية المصنف الحدود وداله توزيع كاوس. حيث اثبتت النتائج الأختباره على افضليه اعتماد طريقة تقارب
